Prophylaxis for Hospitalized and Non-Hospitalized Medical Patients

What it covers
- Who should receive an intervention and what that intervention should be
- Interventions considered include blood thinning medications of different types and mechanical compression (e.g., pneumatic compression devices or graduated compression stockings).

Why it matters
- Medical inpatients, long-term care residents, persons with minor injuries, and long-distance travelers are at increased risk of VTE, which can be fatal (20-25% of all VTE instances occur in these groups).
- It is important to ensure that at-risk patients receive the appropriate measures to prevent VTE without excess bleeding side effects.
- The guidelines recommend the best approaches for preventing VTE in these populations while minimizing unnecessary or over-treatment.

Who it affects
- Medical inpatients (including those in intensive care units), long-term care residents, persons with minor injuries, and long-distance travelers (>4 hours by air)
- Health care providers working in hospitals

What are the highlights
- For patients who are hospitalized, risk assessment for VTE and bleeding help inform a decision on effective prophylactic measures.
- In medical inpatients at high bleeding risk who require prophylaxis, mechanical prophylaxis is preferred over blood-thinning medications.
- In medical inpatients at high VTE risk but acceptable bleeding risk, blood thinning medication is preferred over mechanical prophylaxis.
- In medical inpatients, when medication is used to prevent VTE, low-molecular-weight heparin is preferred over unfractionated heparin because it is only administered once a day and has fewer complications.
- In medical inpatients, when a medication is used to prevent VTE, low-molecular-weight heparin during the hospital stay is preferred over a direct oral anticoagulant administered in hospital or after discharge.
- The use of combined modalities in medical inpatients (e.g., compression devices plus a blood thinner) is not necessary.
- Long-distance air travelers who do not have an elevated risk of thrombosis do not need to wear compression socks or take a blood thinner like aspirin to prevent thrombosis. Air travelers at substantially increased risk may benefit from graduated compression stockings or low-molecular-weight heparin.

Total number of panel recommendations: 21
